Lab 5

TOC to Me

IM Client Implementation --- Part 2
Due: 23:00 Monday 19 October

In this week’s lab we will finish work on the IM client programs you started in the last lab. You will add one significant feature to your program. It will now support multiple chat windows. In addition, you will restructure the internal organization of your program, using classes to more logically organize the instructions.

The chat client you constructed in the last lab displayed all messages sent and received in a single JTextArea. Most real IM clients create a separate window for each buddy with whom messages are exchanged. We would like you to extend your chat client so that it uses multiple windows in this way. Each of these windows will have its own JTextArea for displaying the messages exchanged and a JTextField in which your program’s user can enter messages to be sent to the buddy associated with the window. In addition to these chat windows, your program will display a control window used to log in, log out, and to start a conversation with a selected buddy. A sample of what some of these windows might look like is shown below.

Class Structure

The hardest part of writing a program composed of many classes is usually deciding what functionality to include in each class. This requires deciding which portions of the information needed by the entire program will be kept in each class. This determines what instance variables and what methods are declared in each class.

To simplify the process of writing your first multi-class program, we will provide you with suggestions for the instance variables and methods for each of the classes you should define. As you follow our guidelines, recall that one major goal when dividing a program into classes is to make the structure of the program as clear and logical as possible.
For this program we would like you to define three separate classes:

- **IMControl**: This class will create the control window that displays the fields used to enter the user’s screen name and password, the login and log out buttons, a status field, the menu of buddies and the field and button used to add names to the buddy menu.

- **ChatWindow**: This class will be used to create a window for each conversation that takes place while running your program.

- **TOCServerPacket**: The objects described by this class will not appear as new windows on your screen. Instead, the purpose of this class is to provide a better way to organize some of the code you wrote for the last lab. In particular, this class will provide methods that do the work of extracting screen names and other subfields from the packets sent by AOL’s IM server.

We discuss each of these three classes below.

**IMControl**

Your IMControl class will be quite similar to the class that was your entire program last week. The class will still contain most of the instance variables used to refer to GUI components in last week’s lab. You will still need the text fields and buttons used for entering login information and new buddy names along with the menu used to select a buddy to talk to. The components used to send messages and the components used to see the messages received, however, will be moved to the ChatWindow class. The IMControl class will still have an instance variable associated with the connection to the AOL server.

The only significant addition to the instance variables declared in IMControl will be a variable of type HashMap used to keep track of which ChatWindows are associated with which ongoing conversations. The details of using a HashMap are discussed later in this handout.

You will make three main changes to the methods you defined last time.

- Previously, when the user clicked the send button, an if statement in buttonClicked specified how to send a message. This will be replaced by code to create a new ChatWindow when the user clicks the button to start a new conversation.
- Second, the code in dataAvailable that displayed an incoming message will be replaced by code to notify the appropriate ChatWindow that a message has been received.
- Finally, the code within dataAvailable that examines the subparts of packets received from the server will be revised to use the methods (that you will write) in the TOCServerPacket class.

By the end of this week’s lab, there will be at least three places where you need to normalize screen names. Rather than making three copies of the code to do this, you will define a private method called normalize that takes a screen name (String) as a parameter and returns the normalized version of the argument (i.e., no spaces and all lower case). You should be able to do this fairly easily using the code you wrote to normalize screen names for last week’s lab.

To appropriately align things in your IMControl window, you will add a grid layout. To do so, import java.awt.* at the beginning of your IMControl class. Then you will add a new grid layout to the IMControl window, immediately after creating the window, using an invocation like the following:

```java
this.setLayout( new GridLayout( GRID_ROWS, GRID_COLUMNS ) );
```

Take a look at the IMControl window on page 1 of this document. You want each of the six different JPanels to be stacked one on top of the other, centered. To do this, define GRID_ROWS to be 6 and GRID_COLUMNS to be 1. Then each time you add one of the six JPanels to the contentPane, it will be placed centered in the window on the next row below the previously added JPanel.
ChatWindow
Your ChatWindow class should be designed to create a separate window for each ongoing IM conversation. (See the picture on the first page of this document.)

The constructor for a new ChatWindow should accept three parameters: the normalized screen name of the user, the normalized screen name of the other person involved in the conversation, and the FLAPConnection your program has established with the AOL server. Thus, the construction of a new ChatWindow might look like:

```java
ChatWindow newConversation = new ChatWindow(myName, buddy, toAOL);
```

The ChatWindow class will extend GUIManager. As a result, you can create a new window by invoking createWindow in its constructor just as you invoked createWindow in the constructors of your earlier programs. Your ChatWindow constructor should create a JTextArea (wrapped in a JScrollPane) for displaying messages and a JTextField for entering a message, and add these components to the content pane. Both of these components will be used by methods defined within the class and should therefore be declared as instance variables. In addition, the methods you define will need to use the two screen names and the network connection that are passed as parameters to the constructor. Accordingly, you should define instance variables to refer to these items and include assignment statements within your constructor to associate the instance variable names with the parameter values.

You will only need to define two methods in this class:

- A `textEntered` method should be defined. The code in this method will be automatically executed whenever the user presses return after typing a message into the window’s text field. The code in your `textEntered` method will send the contents of the text field as an IM message and also display it in the ChatWindow’s text area.

- A `messageReceived` method will be defined to handle messages for this conversation received from the AOL server. These messages will actually first be accessed by invoking `in.nextPacket` within the `dataAvailable` method of your IMControl class. The code in `dataAvailable` will need to determine which ChatWindow should display the message (more later on how to do this) and then invoke the `messageReceived` method of that ChatWindow, passing the message as a parameter. The parameter passed to `messageReceived` will be a TOCServerPacket, not a String.

TOCServerPacket
The TOCServerPacket class is intended to provide convenient access to the fields of a packet received from the AOL IM server. Your TOCServerPacket class will provide a constructor and seven public methods: `isError`, `isBuddyUpdate`, `isIncomingIM`, `getBuddyName`, `getBuddyStatus`, `getErrorCode`, and `getMessage`.

The constructor takes the text (String) of a packet received from the server as its parameter. It will store that text in an instance variable for later processing. This is the only instance variable you will need to declare in the TOCServerPacket class.

To construct a TOCServerPacket, you will simply provide a string containing the packet received from the server as a parameter in a TOCServerPacket construction. For example, if the statement

```java
String packetContents = toAOL.in.nextPacket();
```

is used to access a packet from the server, then the construction

```java
TOCServerPacket currentPack = new TOCServerPacket( packetContents );
```

could be used to construct a TOCServerPacket for the data received.
The “is” accessor methods, `isError`, `isBuddyUpdate`, and `isIncomingIM`, return boolean values. They will be used to determine the type of packet received. For example, if the following text was received from

```
IM_IN2:somebuddy:T:T:<html><body>still there? </body></html>
```

and this String was used to create a `TOCServerPacket` named `currentPacket`, then

```
currentPacket.isIncomingIM()
```

will produce `true`, while `currentPack.isError()` and `currentPack.isBuddyUpdate()` will return `false`.

The remaining public methods you will define in this class, `getBuddyName`, `getBuddyStatus`, `getErrorCode` and `getMessage`, will return Strings as results. As their names suggest, each of these methods should extract one of the fields of a packet received from the AOL server. Thus, if `currentPacket` is the packet shown above, the invocation

```
currentPacket.getBuddyName()
```

should produce the String “somebuddy” while the invocation

```
currentPacket.getBuddyStatus()
```

should produce “T”.

The `getMessage` method should do a little more work than the other methods. It should return the actual message included in an IM_IN2 packet. That is, it should return the String found after the fourth colon in an IM_IN2 packet. It should, however, first remove all of the HTML from the message. That is, the loop to remove HTML that you included in the last lab’s `dataAvailable` method should be moved to the method `getMessage` in this class. (Other modifications will be required if you choose to handle displaying HTML as described in the Extra Credit appendix). Assuming `currentPack` refers to the packet described above, the invocation

```
currentPack.getMessage()
```

should return “still there?”. 

The seven methods described above will be the only public methods defined in `TOCServerPacket`. You could implement these methods by simply copying and revising segments of code you wrote last week. Instead, however, we want you to define two private methods described below and then use these methods to simplify the definitions of the public methods.

In class, we have typically extracted substrings by first identifying the positions of both the beginning and end of the desired text and then using a single substring operation. An alternative is to first use substring to remove any unwanted characters from before the desired text and then to use another substring operation to remove unwanted characters from after the desired text. With this in mind, consider defining two private accessor methods named `getPrefix` and `getSuffix`.

The `getPrefix` method will be quite simple. It will take a String as a parameter and return all of the characters in its parameter up to but not including the first colon. If there is no colon, it should return the entire contents of its parameter value. For example:

```
getPrefix( "somebuddy:T:T:<html><body>still there? </body></html>"
)
```

should return “somebuddy”. 

```
The `getSuffix` method will take two parameters: a `String` and an `int` value specifying the number of colon-separated "fields" to remove from the first parameter. It will return the suffix (a `String`) of its first parameter that remains after removing all of the text up to the nth colon where n is the value of the second parameter. For example:

```java
```

should return "somebuddy:T:T:<html><body>still there?</html></body>", while

```java
```

should return "T:T:<html><body>still there?</html></body>", and

```java
```

should return "<html><body>still there?</html></body>". The definition of this method will include a simple loop. Each of the public methods of the TOCServerPacket class can then be easily written by invoking `getSuffix` and `getPrefix`.

**Using HashMaps**

To keep track of which `ChatWindow` goes with which conversation, you will use a class named `HashMap`. The `HashMap` class is included within the standard `java.util` library. Therefore, to use this class you will need to add the line

```java
import java.util.*;
```

to the top of the file containing the definition of your `IMControl` class. Although you'll use a `HashMap` to keep track of `ChatWindows`, the `HashMap` will only be used in the `IMControl` class.

The `HashMap` class is like a dictionary. You can use it to "look up" the `ChatWindow` associated with a buddy name. Of course, `HashMap` isn't included in Java just for implementing IM clients. It can be used to associate values of one type with values of any other type. The way you tell Java what the key (e.g., word or buddy name) and value (i.e., definition or window) types are is to write them in angle brackets when declaring the `HashMap`. Because you want to map buddy names (Strings) to `ChatWindows`, the declaration looks like:

```java
private HashMap<String, ChatWindow> windowList;
```

When creating a `HashMap` with `new`, you need to include those types again:

```java
windowList = new HashMap<String, ChatWindow>();
```

Once a `HashMap` is created, it is very easy to use. To add an item to the collection, you pass the name you want to associate with the item and the item itself as arguments to the `put` method as in:

```java
windowList.put( buddyName, newWindow );
```

You can later ask which window is associated with a given name by using the invocation

```java
windowList.get( buddyName )
```

(If no window is associated with the name you provide as an argument to `get`, the value `null` will be returned as its result. You will use this to determine if you need to create a new chat window.)

You will need to use the `HashMap` in two situations in your program.
When your program receives a new IM_IN2 packet in its dataAvailable method (within the IMControl class), you will use the `get` method to determine if a ChatWindow for that buddy already exists. If no window exists, you will create a new one, and add it to the HashMap using the `put` method. You will then pass the message received to the ChatWindow’s messageReceived method for displaying.

When the user presses the “Start Conversation” button, you will perform a similar lookup, creating a new window only if none already exists for the user selected in the buddy menu. To avoid creating multiple windows for a single buddy, use normalized screen names when you invoke `put` and `get`.

**Getting Started**

Start by making a copy of your project folder from last week’s lab. (If you prefer, a working version of last week’s lab is available on the course Web page.) Rename it so that its name contains your name and “Lab5” (but no blanks). Open this project with Bluej. Then, change the name of your main class to “IMControl” simply by changing the name of the class header and the constructor to `IMControl` and then saving the file. At this point, you will have one class (IMControl) in your project. In the steps below, you will go about modifying that class and defining the two new classes.

**Implementation Plan**

As usual, you should plan to add code to implement one feature at a time and then test each feature before moving on to the next step. The following gives a possible plan for such an approach.

**Implementing the TOCServerPacket class (and modifying dataAvailable inside the IMControl class)**

1. Begin implementing the constructor, the boolean-valued methods, and the private methods of the TOCServerPacket class as outlined in the appendix “Working with Multiple Classes” below.

2. Add definitions of the four public, String-valued methods of the TOCServerPacket class: `getBuddyName`, `getBuddyStatus`, `getErrorCode` and `getMessage`. Test each of these methods by creating an appropriate TOCServerPacket just as you tested the other methods of this class while following the instructions in the “Working with Multiple Classes” section.

3. Modify the code of your `dataAvailable` method to take advantage of your TOCServerPacket class (refer back to page 2 of this document):
   a. As soon as you retrieve a String using the `in.nextPacket` method at the beginning of the `dataAvailable` method you should pass this String as a parameter in a TOCServerPacket construction and associate the TOCServerPacket constructed with a local variable.
   
   b. Replace the invocations of `startsWith` in the branches of the `if` statement that forms the body of your `dataAvailable` methods with conditions that invoke the `isIncomingIM`, `isBuddyUpdate`, and `isError` methods of your TOCServerPacket class using your TOCServerPacket variable.
   
   c. Replace the code you wrote using `indexOf` and `substring` to extract the relevant fields of a message received from the server with invocations of the `getBuddyName`, `getBuddyStatus`, `getMessage`, and `getErrorCode` methods of the TOCServerPacket class.
   
   d. Test your revised program to make sure everything still works as it did before. 
   
   Note: The revised program will provide no functionality beyond what your program provided last week. The purpose of the process of defining and using TOCServerPacket was not to extend what your program could do but instead to simply reorganize its code so that each individual method included in your program would be shorter and simpler.

**Implementing the ChatWindow class (and Modifying IMControl even more)**

4. First, define a private method within the IMControl class that will take a screen name as a parameter and return the normalized version of the name. You already wrote the code to do this last week. Placing it in a private method will enable you to use the code repeatedly without actually repeating it.

5. Define a ChatWindow class with nothing but a constructor that expects no parameters. At this step, just write the code to create the desired GUI interface. You should test this by running it as if it was an independent program.
6. Next, add a `textEntered` method that simply displays anything typed into the text field at the bottom of the `ChatWindow` in its text area. (Also request focus and select all appropriately.)

7. Now add to the constructor parameters that supply the screen names of the sender and recipient of the messages in the window. Modify the invocation of `createWindow` in the constructor so that the recipient’s name will be displayed in the title bar (just pass the title as a third parameter to `createWindow`) and modify `textEntered` so that it places the sender’s name before each message it displays. You should still be able to test this as if it was a single class program. After you select “new `ChatWindow(...)`” from BlueJ’s menu it will let you type in parameter values for it to use. Just type in two names in quotes.

8. Modify your `IMControl` class by removing the message text field and the “Send” button. Replace them with a “Start Conversation” button. Add code to create a new `ChatWindow` when this button is pressed. At this point, it won’t be possible to send messages using your program. You will fix that once you have implemented the ability to manage multiple `ChatWindow`. Also add a status label to the window (see image on page 1). When not logged in, the status should be “Offline”; on an unsuccessful login, the status should be “Login Error”; when logged in, the status should be “Available”. In addition, add a `GridLayout` as described on page 2.

9. Add the code to keep track of the windows created by pressing the “Send” button. Create a `HashMap` (see page 5 of this document) for `ChatWindows` in your `IMControl` constructor. Add code to try to get the window associated with the screen name selected in your buddy menu each time “Start Conversation” is pressed. If a `ChatWindow` is found in the `HashMap`, just make it visible (using the `setVisible` method). Otherwise, create a new window and add it to the `HashMap`. Use normalized screen names.

10. Now, add a `FLAPConnection` parameter to the `ChatWindow` constructor. Declare an instance variable and assign the parameter value to that instance variable. Add code to `textEntered` to actually send a message when the user types one into the window’s text field. Test your program. It should now let you send (but not yet receive) messages through individual `ChatWindow` (but will still display all messages received in the main window’s text area).

11. Add the definition of a `messageReceived` method to `ChatWindow` and modify the code in your `dataAvailable` method to redirect incoming `IM_IN2` messages to the appropriate `ChatWindow`’s `messageReceived` method. To do this, you will have to extract the sender’s name from the `IM_IN2` message (use your `TOCServerPacket` methods!) and try to get the associated `ChatWindow` from the `HashMap`. If no window already exists, you should create a new one and add it to the `HashMap`. Make sure to normalize the screen name. Test your code!

**Clean Up**
Make sure to take a final look through your code checking its correctness and style. Review the comments you received on the work you submitted in previous weeks and make sure you address the issues raised. **Make sure you included your name in a comment in each class definition.**

**Grading**

**Completeness (14 pts) / Correctness (6 pts)**
- GUI layout
- Creating window to start conversation
- Receive message into right window
- Normalize method
- ChatWindow class
- TOCServerPacket method definitions
- `dataAvailable` uses TOCPackets rather than Strings

**Style (10 pts)**
- Commenting
- Good variable names
- Good, consistent indentation
- Good use of blank lines
- Removing unused methods
- Uses public and private methods appropriately

**Submission:** Drop your lab 5 folder into the cmisc150/lab5 folder in the Netfiles inbox of Professor Szajda.
Appendix 1: Working with Multiple Classes

Since this is the first time you will define several distinct classes as part of a single program, we will lead you through the initial steps in the definition of the TOCServerPacket class to show you how you can edit and test the separate classes that make up a multi-class program independently.

When you are ready to create the TOCServerPacket class, click on BlueJ’s “New Class...” button, but do not select GUIManager as the type of class as you have in the past. Instead, leave the type setting as “Class”. BlueJ will respond by creating a class definition with a skeletal constructor and method definition.

Note that the text provided by BlueJ does not include any import directives. This particular class will not use any of the features of Squint or Swing, so it is not necessary to add imports. In general, however, you will have to add imports for any libraries on which the class you are defining depends.

Begin editing this class template by replacing the comments in the first few lines with comments that briefly describe the function of the TOCServerPacket class and include your name. Next, replace the sample instance variable declaration for “x” with a declaration for a String variable that will refer to the text of the TOC packet represented by a particular object of this class. Update the comment that describes the variable while you are at it.

Now, revise the definition of the TOCServerPacket constructor. The constructor in the template includes no formal parameter declarations and sets the (now non-existent) instance variable x equal to 0. Your constructor should expect a String consisting of the contents of a TOC packet as a parameter and should associate the value of this parameter with the String instance variable we told you to define earlier.

Next, replace the definition of sampleMethod with a definition of isIncomingIM. This method’s definition should look like:

```
public boolean isIncomingIM() {
    return your-instance-variable's-name.startsWith( "IM_IN2" );
}
```

with the italicized text replaced the the name you selected for the class’ instance variable.

Provide a similar definition for isBuddyUpdate. Compile your class, fixing any syntax errors reported until it compiles correctly. Now, even though the code you have included is quite simple, let’s test that it works correctly so that you can learn how to test a class like this before trying to use it as part of a larger program.

First, create an instance of the class. The process will be similar to the way you have run programs in past weeks. You will execute the code of your constructor by selecting the “new TOCServerPacket(...)” item from the menu that appears when you depress the “ctrl” key and mouse button while pointing at the tan rectangle that represents the TOCServerPacket class in your program’s project window. When you have selected this item previously, you simply clicked “OK” in the dialog box that appeared. This time, you will have to actually fill in a field within the dialog box before you click “OK”.

Unlike the classes we have defined in past week’s, the constructor for the TOCServerPacket class is defined to expect a parameter. Therefore, when you ask BlueJ to construct a TOCServerPacket it will display a dialog box like the one shown on the right.

In the window that appears, however, the text field above the “OK” button will be empty. BlueJ wants you to fill it in with the String that should be provided as a parameter to the
TOCServerPacket constructor. Type in something that looks like the beginning of a TOC IM_IN2 packet as we have shown in the image on the previous page. The packet does not have to be complete (typing in “...” as shown will actually work), but it must be included in quotes. When you have filled in the parameter value, click “OK”.

In past labs, when you have clicked “OK” in such a dialog box, your program’s window has appeared on the screen. This is because in the constructors of those classes, your code has started with an invocation of createWindow. The TOCServerPacket class does not invoke createWindow. As a result, after you click “OK”, no new window will appear. Instead, all that will happen is that a little red rectangle that looks like:

will appear near the bottom left of your BlueJ project window.

Point the mouse at this icon and depress first the control key and then the mouse button. A menu will appear. The menu should include items that look like “boolean isIncomingIM()” and “boolean isBuddyUpdate()”. Select one of these items. BlueJ should display a new dialog box presenting the result of invoking the method you selected. This box should contain the correct result, true or false. Click “OK”. Now, follow the same procedure to select the menu item for the other method. The box displayed this time should contain the opposite result. If both results were correct, you have tested your methods and you should move on and define the third boolean-valued method required, isError. Once this method is defined, compile the class and test the new method just as we had you test the other methods.

Some of the methods you will have to define in TOCServerPacket are just a bit harder to test because they expect parameters. As an example, consider the getPrefix method. It takes a String as a parameter and returns the characters in the string up to but not including the first colon. Begin by entering the code to define this method. It will require a bit more code than the boolean-valued methods you have already defined. It must use indexOf to find the first colon and then use substring to return the text before this colon. As you write the code for this method think about what it should do if there is no colon.

Ultimately, getPrefix should be a private method. We will not be able to test its behavior using BlueJ’s menus, however, if it is defined this way initially. Therefore, define it as a public method now and then change its definition to private after testing it as described below.

Once you think the method’s definition is complete, compile and fix any syntax errors. To test the method:

1. Begin to create an instance of the TOCServerPacket by selecting “new TOCServerPacket” from the menu that appears when you control-press the mouse while pointing at the TOCServerPacket icon.
2. In the dialog box that appears, type some short String to serve as the sample packet. It doesn’t really matter what you type since the getPrefix method will not use it.
3. After the red icon representing the new TOCServerPacket appears, control-press the mouse on its icon. The menu that appears should contain an item that looks like “String getPrefix( String ... )”. Select this item.
4. Just as BlueJ earlier provided a text field in which you could enter the parameter to be passed to the constructor, it now provides a field for the parameter to the getPrefix method. Fill this field with some quoted String containing one or more colons and press “OK”. Check that the answer is correct. If not, check your code and try again.
5. Be sure to check that your method behaves well on odd cases (a string containing no colon, a string containing no characters at all, ...).

Now, continue in the same manner to define and test each of the other methods required in the TOCServerPacket class following the instructions in the implementation plan.
Appendix 2: Extra Credit Ideas

These optional tricks can increase the functionality of your program. Extra credit can’t take you above the maximum score on the lab, but it can make up for small errors!

1. Make the text wrap:
   The default behavior of the JTextArea is to display the line un-wrapped. If conversation is the name of your JTextArea, change to wrapping with
   
   ```
   conversation.setLineWrap( true );
   ```

2. Make the JTextArea resizable:
   First, you will need to import java.awt.* at the top of your ChatWindow class. Now change the layout manager for your ChatWindow to stretch the JTextArea to fill the window. To do this, include the invocation
   
   ```
   this.setLayout( new BorderLayout() );
   ```
   in your ChatWindow constructor before you add components to the content pane. Once you do this, you will have to add a second parameter when you invoke the content pane’s add method to specify where the component being added should be placed. There are 5 choices: BorderLayout.NORTH, BorderLayout.SOUTH, BorderLayout.WEST, BorderLayout.EAST, and BorderLayout.CENTER. Only one item can be placed in each of these five areas. The item in the center is stretched to fill any space not used by the other four regions. So, placing your text area by
   
   ```
   contentPane.add( conversation, BorderLayout.CENTER );
   ```
   would ensure that it would grow if you increased the window size.

3. Show bold and colored messages by replacing JTextArea with JEditorPane:
   You have seen that the IM messages received from AOL are actually encoded using HTML. We suggested that you should write code to remove this HTML. An alternative is to use a GUI component that knows how to display HTML. The Java JEditorPane is such a component. To use a JEditorPane you will need to:
   
   - Use a BorderLayout as described above.
   - Change the variable you used to refer to your JTextArea to a JEditorPane variable and construct a JEditorPane instead of a JTextArea (the constructor expects no parameters).
   - Assuming the variable’s name is conversation, include the invocation
     
     ```
     conversation.setContentType( "text/html" );
     ```
     in your constructor. Also remove the setLineWrap call discussed above.
   - Revise your code to only remove from a message <html>, <body>, </body> and </html> tags. Any other HTML tags should not be removed.
   - Use setText instead of append to place text in the JEditorPane. This means you will have to keep a separate String variable of the entire conversation (i.e., continually append new messages to this String variable). After each message, append either of the HTML tags <br> or <p>.
   - Make sure that the argument to setText (i.e., the String containing your conversation to display) begins with <html><body> and ends with </body></html>. One way to do this is to define one String containing the prefix (i.e., containing “<html><body>”) and another String containing the suffix (i.e., containing “ </body></html>”) and then pass to setText the prefix String, the conversation String, and the suffix String all appended.
