- INTEGRATED DEVELOPMENT ENVIRONMENTS
- JAVA GENERICS
- ARRAYLIST, MAP
- LAMBIDAS

INTEGRATED DEVELOPMENT ENVIRONMENTS

- IDEs combine the compiler with the text editor
- Many also provide a symbolic debugger to facilitate finding errors
- Lets try HelloWorld together in one, Eclipse

GENERIC PROGRAMMING

- Generic programming – programming in terms of operations of types only. Any type that satisfies the operational constraints may be used.
- In Java – Multiple methods to do this. Polymorphism (at runtime) and Generics (at compile time)
 - A note on Java...no primitive types can be used in generic programming. This is not true of something like C++

PIECE OF CAKE...JUST TREAT EVERYTHING AS AN OBJECT!

```
1. public class GenericArray {
2.     Object[] objs;
3.     ...
4.     /* Other stuff.
5.        But it is limited because Object doesn't offer much.
6.        Still...we can store anything!
7.     */
8.     ...
9. }
```

JAVA GENERICS

- Can be better using “Generics”:

```
1. public class GenericArray<T> { //T is an non primitive type
2.     T[] objs;
3.     /* Make assumptions on the operations of T, e.g.,
4.        all T have function draw(). Now any type that
5.        satisfies this requirement may be used, regardless of
6.        inheritance tree.
7.     */
8. }
```

- Use like:

```
GenericArray<String> = new GenericArray<String> ();
```

Types are explicitly written by the programmer

JAVA GENERICS

- Can also be used in functions:

```
1. public static <T, S> int compare(T t, S s) {  
2.     //make assumptions on the types.  
3.     //Any type that satisfies operation constraints may be used!  
4.     return t.compareTo(s);  
5. }
```

- Used like:

```
1. MyObject1 a;  
2. MyObject2 b; //MyObject1 has function "compareTo(MyObject2)"  
3. int c = compareTo(a, b);
```

Types are implicitly determined by compiler

DATA STRUCTURES

- Data types specifically designed to have “flexible” storage and to do so efficiently
- Here I define some common ones. CMSC 221 delves into how these would be implemented.

“Find out what he’s up to.”

ARRAYLIST

- A “growable” array
- Generic class
- Found in `java.util.ArrayList` (use `import`)
- Common functions: `add`, `remove`, `size`, `contains`
- Can also use related classes `Vector`, `LinkedList`

```
1. import java.util.ArrayList;
2. .../*in the code somewhere*/...
3. ArrayList<String> list =
    new ArrayList<String>();
4. list.add("Hello");
5. list.add("There");
6. list.remove("Hello");
```

MAPS

- Associative containers relate pairs of data, referred to as key, value pairs
- Example: student id to student record
- Provides very fast lookup!
- Can use **HashMap** or **TreeMap** (remember to **import**)
- Common functions: put, get, remove, size, containsKey, containsValue, etc.

```
1. import java.util.HashMap;
2. .../*Somewhere in the code*/...
3. HashMap<Integer, String> h =
    new HashMap<Integer, String>();
4. h.put(4, "JLDiablo");
5. h.put(2, "HelloWorld!");
6. String x = h.get(2);
```

JAVA WILDCARDS

- A very related note, wildcards... “?” represents an unknown type. You can put extends or super constraints on ?, “? **extends** X” or “? **super** Y”, then:

```
1. public static void printArrayList (ArrayList<?> l) {  
2.     for (Object e : l)  
3.         System.out.print (e + " ");  
4. }
```

LAMBDA FUNCTIONS

- Nameless functions, written directly where they are used

- Example:

1. `ArrayList<Integer> numbers = new ArrayList<Integer>();`

2. `for(int i = 0; i < 1000; ++i)`

3. `numbers.add((int) (Math.random()*10000));`

4. `Collections.sort(numbers, (Integer i1, Integer i2) -> i1.compareTo(i2));`
